Impact of age

- Flow = Slow $\propto$ Old
- Complex older people with non-specific presentation in complex systems $\neq$ single system/single problem paradigm
- How do we improve?
Working hard does not improve results

Every system is exactly designed to deliver the result it gets......

- Paul Batalden, Founding Chair, Institute for Healthcare Improvement, Cambridge, MA
Improving ED processes

- Understanding the demand – ambulatory care/ minor illness/ambulance borne older people
- Segmenting the older population
- Staffing with MDT with CGA competency
- Managing geriatric giants: confusion, falls & immobility, polypharmacy, incontinence, end of life care
- Reducing admissions, readmissions, LOS
- Link internally, externally

@P0Banerjee   jb234@le.ac.uk
- Shared vision
- Competency
- Competition time & resources
- Improvement mentality & learning
- Keeping the faith standing under the waterfall
- Moving from a “process” to an “outcomes” mentality
- Money – social care, training
- Community services and primary care resources
The moral imperative.......  
“It was once said that the moral test of government is how that government treats those who are in the dawn of life, the children; those who are in the twilight of life, the elderly; and those who are in the shadows of life, the sick, the needy and the handicapped” (Humphrey Hubert)
The Older Person Standard Set of outcomes

This set is recommended for an older population, however there is no globally agreed definition on what age this is.

As a guideline, the Working Group recommend measuring outcomes for a population which, on average, is in the last 10 years of life based on average life expectancy at age 60 (Global AgeWatch Index 2014):

For example:
- UK: age 84 \(\rightarrow\) \(\geq 74\)
- Japan: age 86 \(\rightarrow\) \(\geq 76\)
- South Africa: age 76 \(\rightarrow\) \(\geq 66\)
- Australia: age 85 \(\rightarrow\) \(\geq 75\)
- Canada: age 85 \(\rightarrow\) \(\geq 75\)
The Older Person Working Group was comprised of international volunteers across six continents.

Frailty index – deficits accumulation

Clinical Frailty Scale*

1. Very Fit – People who are robust, active, energetic and motivated. These people commonly exercise regularly. They are among the fittest for their age.

2. Well – People who have no active disease symptoms but are less fit than category 1. Often, they exercise or are very active occasionally, e.g. seasonally.

3. Managing Well – People whose medical problems are well controlled, but are not regularly active beyond routine walking.

4. Vulnerable – While not dependent on others for daily help, often symptoms limit activities. A common complaint is being “slowed up”, and/or being tired during the day.

5. Mildly Frail – These people often have more evident slowing, and need help in high order IADLS (finances, transportation, heavy housework, medications). Typically, mild frailty progressively impairs shopping and walking outside alone, meal preparation and housework.

6. Moderately Frail – People need help with all outside activities and with keeping house. Inside, they often have problems with stairs and need help with bathing and might need minimal assistance (cuing, standby) with dressing.

7. Severely Frail – Completely dependent for personal care, from whatever cause (physical or cognitive). Even so, they seem stable and not at high risk of dying (within ~ 6 months).

8. Very Severely Frail – Completely dependent, approaching the end of life. Typically, they could not recover even from a minor illness.

9. Terminally Ill – Approaching the end of life. This category applies to people with a life expectancy <6 months, who are not otherwise evidently frail.

Scoring frailty in people with dementia

The degree of frailty corresponds to the degree of dementia. Common symptoms in mild dementia include forgetting the details of a recent event, though still remembering the event itself, repeating the same question/story and social withdrawal.

In moderate dementia, recent memory is very impaired, even though they seemingly can remember their past life events well. They can do personal care with prompting.

In severe dementia, they cannot do personal care without help.

Comprehensive Geriatric Assessment

- Treating 13 frail older people using CGA avoids one unnecessary death or admission to residential care at six months, compared with general medical care for an urgent care episode.

- To put this in perspective, we need to thrombolyse 17 people with acute ischaemic strokes to avoid 1 “unfavourable” outcome same time as causing 1 death for every 100 treated and 1 non-fatal bleed for every 20 treated.
Delivering CGA

- A physician with expertise in the care of frail older people – usually, but not exclusively, a geriatrician
- Physiotherapists and/or occupational therapists
- Nurse specialists that can offer a case management function
- Peripatetic teams with skills and expertise in frailty
- Administrative staff able to organise complex (and simple) discharge
- An area more friendly to older people
- Address outcomes
Leicester

- Emergency Frailty Unit: delivering CGA
- Developing first frailty-friendly ED (summer 2016)
- Front door frailty team – MDT
- Frailty flagging
- Delirium screening
- UTI project
- PHEM GEM link with "Clinical Hub"
